Tittle	Predicting mobile trading system discontinuance: The role of attention
Havard Reference	Kim, D., Park, K., Lee, D.J. and Ahn, Y. (2020). 'Predicting mobile trading system discontinuance: The role of attention', *Electronic Commerce Research and Applications*, 44, 101008.
Link	ScienceDirect - publication
Modelling	• Logistic Regression • XGBoost, a gradient-boosting tree model • Artificial Neural Network • RFM framework
Preprocessing techniques	• The researchers started with detailed transaction history, usage information and login timestamps. • They focused on retail investors and removed accounts identified as professional traders • The paper highlights removing the top 1% of accounts by trading frequency in 2017. • Behavioural features including RFM measures and mobile attention measures such as number of logins and number of login days were created from transaction and login data.

Datasets used	• They used proprietary data from a major Korean financial-services company. • Data covered January 2017 to June 2018. • The broader dataset contained 458,098 retail-investor accounts • The modelling study analysed about 25822 mobile-trading users. • Variables include gender, age, trading history, trading channel and login information.
Key takeaways	• Login behaviour is useful for predicting future inactivity. • RFM-style behavioural features are valuable. • XGBoost consistently outperformed the benchmark approaches in this study.

2.

Tittle	From engagement to retention: Unveiling factors driving user engagement and continued usage of mobile trading apps
Havard Reference	Thapa, S., Panda, S., Ghimire, A. and Kim, D.J. (2024). 'From engagement to retention: Unveiling factors driving user engagement and continued usage of mobile trading apps', *Decision Support Systems*, 183, 114265.

Link	ScienceDirect - publication
Modelling	• Study 1: semi-structured interviews • Study 2: survey of stock-trading-app users • The study used a behavioural framework based on the Stimulus Organism Response (SOR) theory. • It tested relationships between app features, customer engagement and continued usage intention.
Preprocessing techniques	• Qualitative interview responses were first used to identify important engagement factors. • Survey responses were then used in the quantitative stage to test the proposed relationships. • The study focused on measurement of constructs such as social presence, security, service quality, data analytics, uncertainty and perceived corporate hypocrisy
Datasets used	• No publicly available transaction dataset. • Semi-structured interviews with stock trading app users. • Survey responses from users recruited through three Facebook stock-trading communities.
Key takeaways	• A user registering for an app is not necessarily a user who will continue using it. • Security, social presence and data-related features were associated with engagement.

3.

Tittle	Leveraging machine learning for predictive insights in robo-advisory adoption: a marketing analytics approach

Havard Reference	Bai, Z. (2026). 'Leveraging machine learning for predictive insights in robo-advisory adoption: a marketing analytics approach', *Journal of Marketing Analytics*, 14, pp. 460–473. Published online on 21 November 2024.
Link	Springer Nature - puplication
Modelling	• Logistic Regression • Classification Tree • Random Forest • Boosting • Different probability thresholds were examined for Logistic Regression
Preprocessing techniques	• The study extracted relevant variables from the 2015 National Financial Capability Study. • Variables represented demographic characteristics, financial knowledge, attitudes and other financial behaviours. • The article's main methodological emphasis is model comparison and prediction. • The study constructed measures such as financial knowledge and used categorical and numerical predictors in the models.
Datasets used	• 2015 National Financial Capability Study (NFCS2015).
Key takeaways	• Logistic Regression performed best for investment related prediction. • Age was an important predictor in both logistic and tree-based models. • The influence of financial knowledge differed for different age groups.

4.

Tittle	A comprehensive dataset of customer behavior in Latin American Fintech: 12-month transactional and demographic data for churn analysis.
Havard Reference	Muñoz-Guerrero, L.E., Ceballos, Y.F. and Trejos-Rojas, L.D. (2026). 'A comprehensive dataset of customer behavior in Latin American Fintech: 12-month transactional and demographic data for churn analysis', *Data in Brief*, 65, 112484
Link	ScienceDirect - publication Dataset
Modelling	• No machine-learning model was applied.
Preprocessing techniques	• Data was collected from CRM and transaction databases through automated API extraction, app usage and conducting surveys. • Identified and analysed statistical outliers • Aggregated geographic information to protect privacy • Created new behavioural variables, including transaction frequency, churn probability and customer lifetime value.
Datasets used	• COFINFAD (Colombian Fintech Financial Analytics Dataset).
Key takeaways	• The combination of transaction, customer and digital-engagement information gives a better understanding of customer behaviour • Behavioural measures such as transaction frequency, recency, app-login activity and product usage are essential for identifying customer activity patterns.
